Abstract :

Geo social networked data might be one of the great resource towards on the creation of dynamic decisions and future predictions analyzed by the critical geosocial situation. Many Geosocial Network users produced to overwhelming data, such data is specified as “Big Data” which is necessary required to be analyze and formulate dynamic assessment. The proposed system architecture processes plentiful sum of diversified social networks’ data to analyze many issues like, natural calamities, chronic ailments and current developments in natural activities like, infrastructure and construction up gradation domain, GDP growth, fashion, agricultural products progressions, etc. to create future decisions and impede out looked plans. The proposed architecture is used to analyzed the Twitter network in order to categorize the present proceedings to analyze the data effectiveness based on throughput of a system.

Keywords: - Social media, Twitter Analysis, data Analytics, MapReduce

I. INTRODUCTION

Because of technological up gradation now a day’s social network is significantly advanced and transformed into Geo social connectivity. Significantly geo social media provides an competent authority and popularity in the network to end user based on their worthwhile content along with their geographical information, which has inference towards on the proper usage of Geo social networks. The information sharing towards on geo social media is based on,

1. Amalgamation of generic content in web post, it specifies the geographical sequence based on their current position of the usage i.e. by finding the Earth coordinates, like altitude and latitude.
2. User reviews are represented on social networks revealed the activities, affiliation, association, communication and social knowledge between the users.

Now a day’s Blog websites have progressed to turn out to be a multi functional resources with variety of informational kind, i.e. in blog users

will post actual and concurrent messages about their feelings and impressions on variety of subjects with specific matters, like, discussing with concurrent issues, criticize, and articulate positive as well as negative sentiment analysis on a daily basis usage of their existence. In this regard community researchers can study user reactions, sentiments and respond to the specific users on blogs, but the major challenge towards the blog is to construct, identify, review and analyze overall response of the specific user sentiments.

A. *Big Data*

Big data is collection of data set with huge size, complexiveness and dynamic in range, where it is very complicated to be capture, manage, process or analyzed by the traditional processing tools like, RDBMS and its packages.

B. *Challenges with Big Data Processing are*

1) **Heterogeneity**

When humans consume information, a great deal of heterogeneity is comfortably tolerated. In fact, the nuance and richness of natural language can provide valuable depth, i.e. Computer systems work most efficiently if they can store multiple items that are all identical in size and structure.

2) **Scalability**

Managing large and rapidly increasing volumes of data has been a challenging issue for many decades where data volume is scaling faster than compute resources, and CPU speeds are static.

3) **Timeliness**

The flip side of size is speed. The larger the data set to be processed, the longer it will take to analyze. The design of a system that effectively deals with size is likely also to result in a system that can process a given size of data set faster.

4) **Confidentiality**

Managing confidentiality is effectively both a technical and a sociological problem, which must be addressed jointly from both perspectives to realize the promise of big data.

5) **User Cooperation**

Ideally, analytics for Big Data will not be all computational rather it will be designed explicitly to have a human in the loop. A Big Data analysis system must support input from multiple human experts, and shared the exploration of results.

II. **LITERATURE REVIEW**

Information gathering and examination of the resources corresponds to supplementary prominent plan and comprehension towards the development of user prospects.

The data scattered through such media speaks to a deviation from volunteered geology, i.e. the areas from where the tweets start, or references in their substance to geographic substances [1].

The Online networking sustained and developed as a novel method for the commitment and dispersal of data on regular geographic in nature, i.e. it collects the references to occasions are happened at, or influenced on specific areas, i.e. momentary qualities of the twitter [2].

Crisis Camp Haiti, Open Street Map, Ushahidi, and Geo Commons are discussed in this paper, and they examine that IT is a key means of geospatial model through which people could have communicate each other not physical presence [3].

In this paper author design to survey and present the capability of innovation to the urban development and arranging group. Moreover, they showcased 'Mobile Landscapes' venture: an application in the metropolitan territory of Milan, Italy, in view of the geological mapping of wireless utilization at various circumstances of the day [4].

Programming design find to deciding how best to tract a framework, how parts distinguish and speak with each other, how data is imparted, how components of a framework can develop freely, and how the greater part of the above can be depicted utilizing formal and casual documentations. [5]

III. PROPOSED COMPUTATIONAL MODEL

Above computational model illustrate the overview of the system, architectural components, system applications and its limitations are defined, where the proposed system analyze and calculate all tweets generated by Twitter users.

Based on the computations in twitter analysis user will get so specific information about location and dynamic monitoring on natural calamities, chronic diseases, mega accidents, products, popular hotels, malls and transportations.

A. Map-Reduce Architecture

In specific Big data application MapReduce framework be the computational stake in the Hadoop environment, where system will allows all specification about operations, its applied on huge data set. MapReduce technique will divide the application into tiny chunks of data sets but it run in concurrent mode in a system.

From developer view point, MapReduce technique can occur in multi fold measurements, i.e. big datasets can be cut down into tiny data subsets, where data analytics is takes place. In Hadoop ecosystem MapReduce programs will interface data streams to write and run on tiny datasets within local system.

Fig 1 shows the MapReduce computational model, where users can define two operations:

- **map** operation - it alter, filter, or select input data
- **reduce** operation - it aggregate, combine, or collect data.

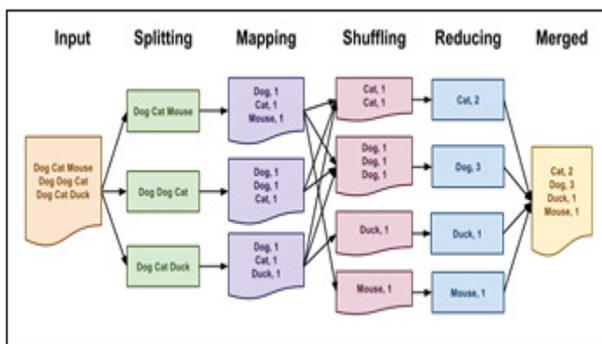

Fig 1: MapReduce Architecture

The proposed system gather user data from Geosocial Networks as a record with attributes (l, t, u) , where location – l, time – t, and user – u, here the record explains which user U is post information on Geosocial Network at particular time t, from which location l. usually in all web application gathering of user location

is a demanding task but it is so easy because of advanced smart devices and GPS systems.

Fig.2 shows the system architecture for geospatial computation, where the system consists of three layers: geospatial big data integration & management, geospatial big data analytics, and geospatial big data service platform. The first layer is a application layer, it is responsible for store, retrieve, index, and search the geospatial data. The second layer is geospatial visualization tools, it is responsible for perform the data analysis, it is further divided into several modules for the intense of interactive analysis of real-time or dynamic data.

IV. RESULT ANALYSIS

In the experimental analysis of the system analyze and compute the tweets produced by the twitter users, where all information communicate to the user locations and user will get so specific information about location and dynamic monitoring on natural calamities, chronic diseases, mega accidents, products, popular hotels, malls and transportations.

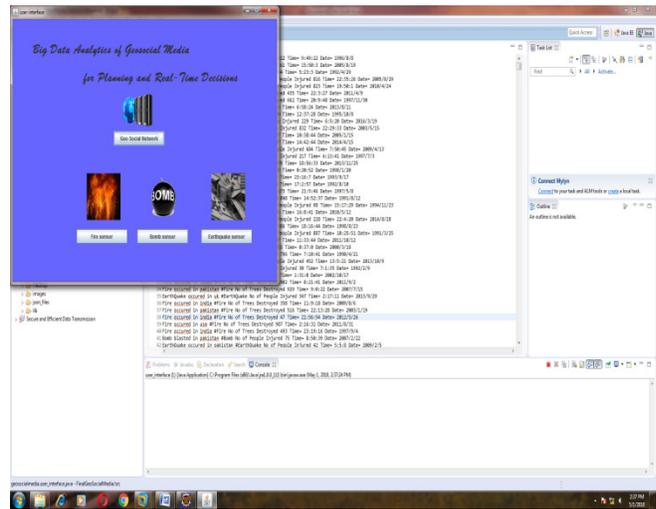

Fig 3: snapshot shows the user interface and click on Geo Social Network button

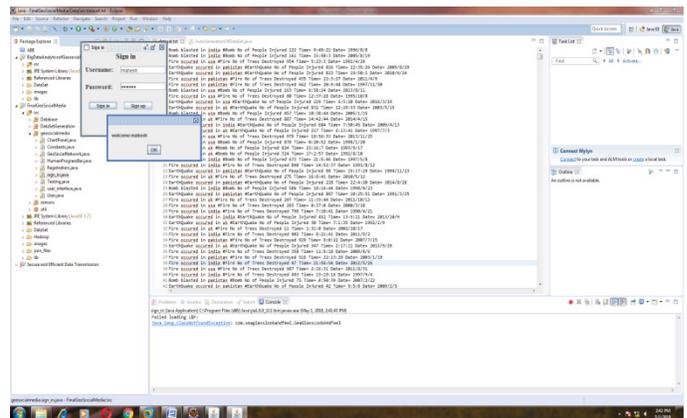

Fig 4: snapshot shows login

unscrambling Time taken for specific occasion information.

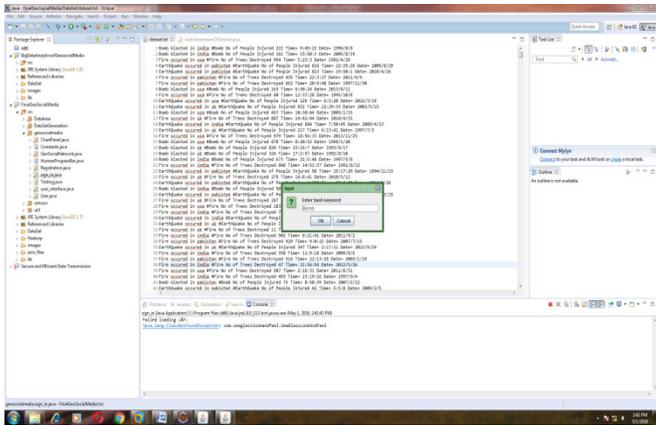

Fig 5: snapshot shows user has to enter the hash keyword

As shown in Figure 9.15 shows how to enter the hash keyword hash keywords are like Fire,Bomb,EarthQuake.

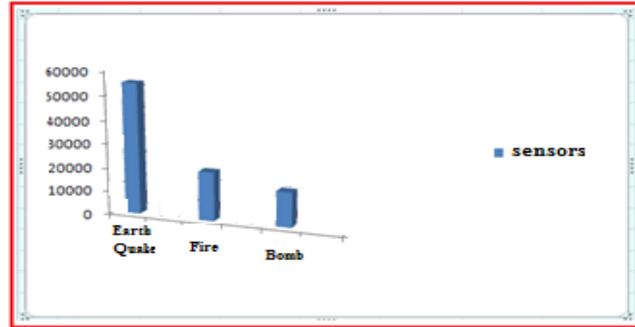

Fig 7 Number of tweets of each events

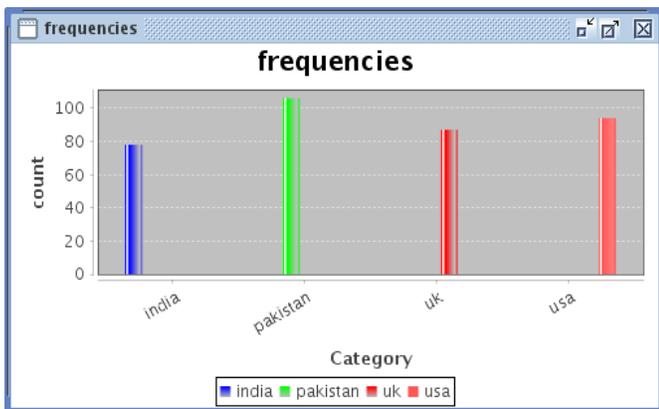

Fig 6: snapshot shows the result with graph

As shown in Figure 9.18 shows the final result of in which places how many times the Fire or Bomb or Earthquake is occurred.

To analyze the proposed system we are using the Twitter dataset which can contains the various disaster information like earth quake, fire, Bomb event we are using dataset from year 2000 to 2010. We are analyzing the all Twitter tweets. The investigation is led in view of the client hunting down which specific occasion. Here we are additionally indicating outcomes for diagram of Encryption time and

V. CONCLUSION

Geosocial network has proved that it is an asset to reforms of the society. Social Media provide for rapid promising technique as a social opportunity for propagation of geographical and geolocal information as social media content, it normally includes the specific location and various keywords in web sites.

Analysis of the twitter information feeds to geospatial computing and treat the users as a sensor, so retrieval of information is too fast and interesting as usual. The aim of this project is to study and evaluate the quality of the tweets from voluminous amount of data, where the review further helps us to augment the advanced situational awareness to users.
